

# Assignment - 1

1-(a) I have defined 2-D array named dp in which  $dp[a][b]$  denotes the probability of Alice winning a matches and Bob winning b matches.

We know Bob and Alice have each already won 1 match.

Therefore  $dp[1][1] = 1$  [Base Case]

Therefore if  $a > 1$

$$dp[a][b] = dp[a][b] + dp[a-1][b] \times \frac{b}{a+b-1}$$

Since both attack

When both attack probability of Alice winning

$$= \frac{n_b}{n_a + n_b}$$

↖ Alice's correct hits      ↗ Bob's correct hits

And Bob's Alice had to win this match  
Bob's point = b  
Total = a + b - 1  
[Excluding this round]

Also if  $b > 1$

$$dp[a][b] = dp[a][b] + dp[a][b-1] \times \frac{a}{a+b-1}$$

When both attack probability of Bob winning

$$= \frac{n_a}{n_a + n_b}$$

→ Alice's correct hits

Probability of Bob winning (a+b)th match

Entry no. = 0625

$$T_1 T_2 = 96, T_3 T_4 = 25$$

$$T = 121$$

replaced by 9

We have used mod Operation in between.

$$\text{calc} - \text{prob}(96, 25) = 0.8639988$$

1b) Let us consider  $(X_1 + X_2 + X_3 + \dots + X_n)$  as a new random variable

Since 2 matches are already played, so there are  $n-2$  matches left  
 Alice can only score maximum of  $n-2$  points  
 minimum of  $2-n$  points

So Heeding through the possibilities from  $-(n-2)$  to  $n-2$   
 we get is the value of  $X_1 + X_2 + \dots + X_n = i$

the prob if Alice won  $y$  matches and lost  $y$  matches

$$n - y = i$$

$$n + y = n \quad \text{[Since probability of drawing 0 when they both attack each]}$$

$$n = \frac{n+i}{2}$$

$$y = \frac{n-i}{2}$$

$\therefore (n+i)$  is divisible by 2

$$ans = ans + i \times \text{probability} \left( \text{Alice winning } \frac{n+i}{2} \text{ matches, losing } \frac{n-i}{2} \text{ matches} \right)$$

This gives the expectation which apparently converges to 0 in all cases.

Similarly for the variance

$$Var(X_1 + X_2 + \dots + X_n) = E((X_1 + X_2 + \dots + X_n)^2) - (E(X_1 + X_2 + \dots + X_n))^2$$

in this similarly to calculating expectation of  $X_1 + X_2 + \dots + X_n$  we add multiplication of probability with  $i^2$

$$\therefore ans = ans + i^2 \times \text{probability} \left( \text{Alice winning } \frac{n+i}{2} \text{ matches, losing } \frac{n-i}{2} \text{ matches} \right)$$

This is done from  $i = -n+2, -n+4, \dots, n-2$

To find variance we find  $E(X^2) - (E(X))^2$

For  $T_3 T_4 = 25$  value comes out to be 333333344  
[binomial form]

2a If Bob defends, expectation of points in diff strategies of Alice

$$\text{Attack} := \frac{5}{11} \times 1 + 0 \times \frac{1}{2} + 0 \times \frac{6}{11} = \frac{5}{11}$$

$$\text{Balanced} := \frac{3}{10} \times 1 + \frac{1}{2} \times \frac{1}{2} + 0 \times \frac{1}{3} = \frac{6}{20}$$

$$\text{Defence} := \frac{1}{10} + \frac{2}{3} + 0 = \frac{1}{2}$$

$\therefore$  Balanced strategy to be followed as it gives the maximum expected points.

If Bob balances,

$$\text{Attack} := \frac{7}{10} + 0 \times \frac{1}{2} + \frac{3}{10} \times 0 = \frac{7}{10}$$

$$\text{Balanced} := \frac{1}{3} + \frac{1}{2} \times \frac{1}{3} + 0 \times \frac{1}{3} = \frac{1}{2}$$

$$\text{Defence} := \frac{1}{3} + \frac{1}{2} \times \frac{1}{2} + \frac{3}{10} \times 0 = \frac{9}{20}$$

Clearly Alice should attack as it gives maximum expected points

If Bob attacks

$$\text{Attack} := \frac{m_B}{n_A + n_B}$$

$$\text{Defence} := \frac{6}{11}$$

$$\text{Balanced} = \frac{3}{10}$$

Depending on values of  $n_A, n_B$ , Alice should either attack or defend

$$\text{If } \frac{n_A}{n_A + n_B} > \frac{6}{11} \Rightarrow \begin{aligned} 11n_A &> 6n_A + 6n_B \\ 5n_A &> 6n_B \end{aligned}$$

Alice should attack  
else it should defend.

2c We carry out simulation until we get  $T$  wins for this setup is reset before which we take note of the no. of moves taken to get  $T$  wins. Then we add all values to get  $T$  wins and divide it by total no. of setup observed. This gives desired expectation.

for  $t_n = 25$  we get expectation as 51.42137

3a Here Bob randomly chooses to attack/ balance/ defend.

If Alice attacks then his expectation of points is:

$$\begin{aligned} & \frac{1}{3} \times \frac{n_B}{n_A + n_B} + \frac{7}{10} \times \frac{1}{3} + \frac{5}{11} \times \frac{1}{3} \\ & \text{[Bob attacks]} \quad \text{[Bob balances]} \quad \text{[Bob defends]} \\ & = \frac{127}{330} + \frac{1}{3} \frac{n_B}{n_A + n_B} \end{aligned}$$

If Alice balances then his expectation of points is:

$$\begin{aligned} & \frac{1}{3} \times \frac{2}{10} + \frac{1}{3} \times \left[ \frac{1}{3} + \frac{1}{2} \times \frac{1}{3} \right] + \frac{1}{3} \times \left[ \frac{3}{10} + \frac{1}{2} \times \frac{1}{2} \right] \\ & \text{[Bob attacks]} \quad \text{[Bob balances]} \quad \text{[Bob defends]} \\ & = \frac{27}{20} \end{aligned}$$

if Alice defends,

$$\frac{1}{3} \times \left[ \frac{6}{11} \right] + \frac{1}{3} \times \left[ \frac{1}{3} + \frac{1}{2} \times \frac{1}{2} \right] + \frac{1}{3} \times \left[ \frac{1}{10} + \frac{1}{2} \times \frac{4}{5} \right]$$

↓ Bob Attacks
↓ Bob balances
↓ Bob defends

$$= \frac{2}{11} + \frac{3}{20} + \frac{1}{6} = \frac{66}{660} + \frac{99}{660} + \frac{110}{660} = \frac{221}{660}$$

∴ He either defends or attacks depending on  $n_A, n_B$ 's

if  $29 \cdot n_A < 15 \cdot n_B$ :  $29 \cdot n_B > 15 \cdot n_A$   
 he Alice will ~~defend~~ attack  
 else he will ~~attack~~ defend.

3a In 3b, we found out the dp table in which the state is defined as points of Alice, points of Bob and the rounds remaining.

Base Case  $\rightarrow$  when rounds remaining = 0, Expected points of Alice = 1

Now when ~~expected~~ we find the max of expectation when Alice attacks, defends or balances,

$$\begin{aligned} \text{Expected value} = & p_{\text{win}} * \text{max exp.}(n_A+1, n_B, \text{total}-1) \\ & + p_{\text{draw}} * \left( \frac{1}{2} * \text{max exp.}(n_A+0.5, n_B+0.5, \text{total}-1) \right) \\ & + p_{\text{lose}} * \text{max exp.}(n_A, n_B+1, \text{total}-1) \end{aligned}$$

So the best of expectation is taken and stored in a dp table.

In dp-table since we need integers

we store ~~the~~  $2 \cdot$  points [as possibility of 0.5 in points]

Also we found estimated value of expectation value using Monte Carlo using the greedy approach and compared the expectation value of both.  
Our dp approach turns out to be better. It is proved in the end.

2b We know that there are two types of strategies, deterministic and non deterministic.

In <sup>non</sup> deterministic strategy, since expectation is further out to be expected which is itself probabilistic. Therefore the terms found in deterministic strategy is to be kept but in non deterministic strategy, smaller terms have some probability to appear which make it worse than deterministic strategy.

In deterministic strategy, best is that at dp and in this case it comes out to be similar to that of non deterministic strategy.

Therefore our greedy approach gives the best result.

Although while simulating we also got different strategies which were better but finally the expectation of greedy turned out to be best.
